2.3 Assume that a golf ball occupies the space equivalent to a 2 in \times 2 in \times 2 in cube. For a classroom with dimensions 40 ft \times 40 ft \times 15 ft :

$$n_{\text{balls}} = \frac{40 \times 40 \times 15 \text{ ft}^3 \mid (12)^3 \text{ in}^3 \mid 1 \text{ ball}}{\text{ft}^3 \mid 2^3 \text{ in}^3} = 5.18 \times 10^6 \approx \underline{\underline{5 \text{ million balls}}}$$

The estimate could vary by an order of magnitude or more, depending on the assumptions made.

CHAPTER FOUR

4.1 a. Continuous, Transient

- b. Input – Output = Accumulation
No reactions \Rightarrow Generation = 0, Consumption = 0

$$6.00 \frac{\text{kg}}{\text{s}} - 3.00 \frac{\text{kg}}{\text{s}} = \frac{dn}{dt} \Rightarrow \underline{\underline{\frac{dn}{dt} = 3.00 \frac{\text{kg}}{\text{s}}}}$$

c. $t = \frac{1.00 \text{ m}^3}{1 \text{ m}^3} \left| \frac{1000 \text{ kg}}{3.00 \text{ kg}} \right| \frac{1 \text{ s}}{1} = \underline{\underline{333 \text{ s}}}$

4.2 a. Continuous, Steady State

b. $k = 0 \Rightarrow \underline{\underline{C_A = C_{A0}}} \quad k = \infty \Rightarrow \underline{\underline{C_A = 0}}$

- c. Input – Output – Consumption = 0
Steady state \Rightarrow Accumulation = 0
A is a reactant \Rightarrow Generation = 0

$$\dot{V} \left(\frac{\text{m}^3}{\text{s}} \right) C_{A0} \left(\frac{\text{mol}}{\text{m}^3} \right) = \dot{V} \left(\frac{\text{m}^3}{\text{s}} \right) C_A \left(\frac{\text{mol}}{\text{m}^3} \right) + kVC_A \left(\frac{\text{mol}}{\text{s}} \right) \Rightarrow \underline{\underline{C_A = \frac{C_{A0}}{1 + \frac{kV}{\dot{V}}}}}$$

4.3 a.

(1) Total Mass Balance: $100.0 \text{ kg/h} = \dot{m}_v + \dot{m}_l$

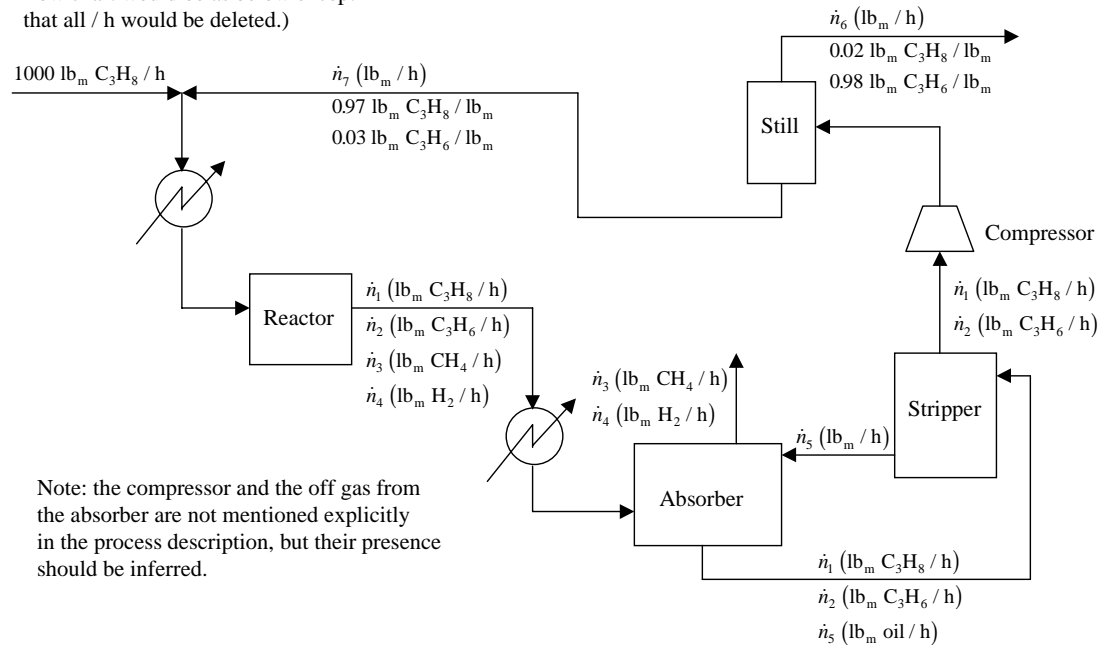

(2) Benzene Balance: $[0.550 \times 100.0] \text{ kg B/h} = 0.850\dot{m}_v + 0.106\dot{m}_l$

Solve (1) & (2) simultaneously $\Rightarrow \underline{\underline{\dot{m}_v = 59.7 \text{ kg/h}, \dot{m}_l = 40.3 \text{ kg/h}}}$

- b. The flow chart is identical to that of (a), except that mass flow rates (kg/h) are replaced by masses (kg). The balance equations are also identical (initial input = final output).
- c. Possible explanations \Rightarrow a chemical reaction is taking place, the process is not at steady state, the feed composition is incorrect, the flow rates are not what they are supposed to be, other species are in the feed stream, measurement errors.

- 4.4 b. $\frac{n(\text{mol})}{0.500 \text{ mol N}_2/\text{mol} \quad 0.500 \text{ mol CH}_4/\text{mol}} \rightarrow \frac{0.500n(\text{mol N}_2)}{\left| \frac{28 \text{ g N}_2}{\text{mol N}_2} \right| \frac{1 \text{ kg}}{1000 \text{ g}}} = \underline{\underline{0.014n(\text{kg N}_2)}}$

(Could also take 1 h operation as basis - flow chart would be as below except that all / h would be deleted.)

4.5 (cont'd)

- b. Overall objective: To produce C_3H_6 from C_3H_8 .
Preheater function: Raise temperature of the reactants to raise the reaction rate.
Reactor function: Convert C_3H_8 to C_3H_6 .
Absorption tower function: Separate the C_3H_8 and C_3H_6 in the reactor effluent from the other components.
Stripping tower function: Recover the C_3H_8 and C_3H_6 from the solvent.
Distillation column function: Separate the C_3H_5 from the C_3H_8 .

4.6 a. 3 independent balances (one for each species)

- b. 7 unknowns ($\dot{m}_1, \dot{m}_3, \dot{m}_5, x_2, y_2, y_4, z_4$)
 – 3 balances
 – 2 mole fraction summations
 2 unknowns must be specified

c. $\underline{y_2} = 1 - x_2$

A Balance: $5300x_2 \left(\frac{\text{kg A}}{\text{h}} \right) = \left[\underline{\dot{m}_3} + (1200)(0.70) \right] \left(\frac{\text{kg A}}{\text{h}} \right)$

$\underline{z_4} = 1 - 0.70 - y_4$

4.7 a. 3 independent balances (one for each species)

b. Water Balance: $\frac{400 \text{ g}}{\text{min}} \left| \frac{0.885 \text{ g H}_2\text{O}}{\text{g}} \right| = \frac{\underline{\dot{m}_R} (\text{g})}{(\text{min})} \left| \frac{0.995 \text{ g H}_2\text{O}}{\text{g}} \right| \Rightarrow \underline{\dot{m}_R} = 356 \text{ g/min}$

Acetic Acid Balance: $[(400)(0.115)] \left(\frac{\text{g CH}_3\text{OOH}}{\text{min}} \right) = [0.005\dot{m}_R + 0.096\underline{\dot{m}_E}] \left(\frac{\text{g CH}_3\text{OOH}}{\text{min}} \right)$

c. $n_1 + n_2 = 50$ large eggs/min

$$n_1 \text{ large eggs broken} / 50 \text{ large eggs} = (11/50) = 0.22$$

d. 22% of the large eggs (right hand) and $(25/70) \Rightarrow 36\%$ of the extra-large eggs (left hand) are broken. Since it does not require much strength to break an egg, the left hand is probably poorly controlled (rather than strong) relative to the right. Therefore, Fred is right-handed.

4.11 a.

b. Propane feed rate: $0.0403\dot{n}_1 = 150 \Rightarrow \dot{n}_1 = 3722 (\text{mol} / \text{s})$

Propane balance: $0.0403\dot{n}_1 = 0.0205\dot{n}_3 \Rightarrow \dot{n}_3 = 7317 (\text{mol} / \text{s})$

Overall balance: $3722 + \dot{n}_2 = 7317 \Rightarrow \underline{\underline{\dot{n}_2 = 3600 (\text{mol} / \text{s})}}$

- c.** \geq . The dilution rate should be greater than the value calculated to ensure that ignition is not possible even if the fuel feed rate increases slightly.

4.12 a.

Output: $(0.861 \text{ kg P / kg})(1239 \text{ kg}) + (0.123 \text{ kg P / kg})(1014 \text{ kg}) = 1192 \text{ kg P}$

The P balance does not close. Analyzer readings are wrong; impure feed; extrapolation beyond analyzer calibration data is risky -- recalibrate; get data for $R > 583$; not at steady state; additional reaction occurs in purifier; normal data scatter.

For a given SO₂ feed rate removing more SO₂ (lower y_3) requires a higher solvent feed rate (\dot{V}_2).

For a given SO₂ removal rate (y_3), a higher solvent feed rate (\dot{V}_2) tends to a more dilute SO₂ solution at the outlet (lower x_4).

Solution: $C_{Ai} = \frac{-\beta + \sqrt{\beta^2 - 4\alpha\gamma}}{2\alpha}$ (Only + rather than \pm : since $\alpha\gamma$ is negative and the negative solution would yield a negative concentration.)

b. If more air is fed to the furnace,

- (i) more gas must be compressed (pumped), leading to a higher cost (possibly a larger pump, and greater utility costs)
- (ii) The heat released by the combustion is absorbed by a greater quantity of gas, and so the product gas temperature decreases and less steam is produced.

- c. Increase yield by raising pressure, lowering temperature, increasing H_{ss} . Increasing the pressure raises costs because more compression is needed.
- d. If the temperature is too low, a low reaction rate may keep the reaction from reaching equilibrium in a reasonable time period.
- e. Assumed that reaction reached equilibrium, ideal gas behavior, complete condensation of methanol, not steady-state measurement errors.

Given T , V_o , h , find d

Initial: $n_o = \frac{V_o}{RT} \quad (P_o = 1)$

Final: $V = V_o + \frac{\pi d^2 h}{4}$, $n = n_o + \frac{3.63 \text{ (kg)}}{44 \text{ (kg / kmol)}} = \frac{V_o}{RT} + 0.0825$

$$\hat{V} = \frac{V}{n} = \frac{V_o + \frac{\pi d^2 h}{4}}{\frac{V_o}{RT} + 0.0825}$$

$$P = \frac{W}{A_{\text{piston}}} = \frac{RT}{\hat{V} - b} - \frac{\alpha a}{\hat{V}(\hat{V} + b)} \Rightarrow \frac{53,900}{\pi d^2 / 4} = \frac{RT}{\hat{V} - b} - \frac{\alpha a}{\hat{V}(\hat{V} + b)} \quad (1)$$

Substitute expression for \hat{V} in (1) \Rightarrow one equation in one unknown. Solve for d .

5.62 a. Using ideal gas assumption:

$$P_g = \frac{nRT}{V} - P_{\text{atm}} = \frac{35.3 \text{ lb}_m \text{ O}_2}{32.0 \text{ lb}_m} \left| \frac{1 \text{ lb-mole}}{\text{lb-mole}} \right| \frac{10.73 \text{ ft}^3 \cdot \text{psia}}{\text{lb-mole} \cdot ^\circ\text{R}} \left| \frac{509.7^\circ\text{R}}{2.5 \text{ ft}^3} \right| - 14.7 \text{ psia} = \underline{\underline{2400 \text{ psig}}}$$

b. SRK Equation of state: $P = \frac{RT}{(\hat{V} - b)} - \frac{\alpha a}{\hat{V}(\hat{V} + b)}$

$$\hat{V}_{\text{ideal}} = \frac{2.5 \text{ ft}^3}{35.3 \text{ lb}_m} \left| \frac{32.0 \text{ lb}_m / \text{lb-mole}}{\text{lb-mole}} \right| = 2.27 \frac{\text{ft}^3}{\text{lb-mole}}$$

(Use as a first estimate when solving the SRK equation)

For O_2 : $T_c = 277.9^\circ\text{R}$, $P_c = 730.4 \text{ psi}$, $\omega = 0.021$

$$a = 5203.8 \frac{\text{ft}^6 \cdot \text{psi}}{\text{lb-mole}^2}, \quad b = 0.3537 \frac{\text{ft}^3}{\text{lb-mole}}, \quad m = 0.518, \quad \alpha(50^\circ\text{F}) = 0.667$$

$$(2400 + 14.7) \text{ psi} = \frac{\left(10.73 \frac{\text{ft}^3 \cdot \text{psi}}{\text{lb-mole} \cdot ^\circ\text{R}}\right)(509.7^\circ\text{R})}{\left(\hat{V} - 0.3537\right) \frac{\text{ft}^3}{\text{lb-mole}}} - \frac{(0.667)(5203.8 \frac{\text{ft}^6 \cdot \text{psi}}{\text{lb-mole}^2})}{\hat{V}(\hat{V} + 0.3537) \frac{\text{ft}^6}{\text{lb-mole}^2}}$$

$$\text{E-Z Solve} \Rightarrow \hat{V} = 2.139 \text{ ft}^3 / \text{lb-mole}$$

5.62 (cont'd)

$$m_{O_2} = \frac{V}{\hat{V}} MW = \frac{2.5 \text{ ft}^3}{2.139 \text{ ft}^3 / \text{lb-mole}} \left| \frac{32.0 \text{ lb}_m}{\text{lb-mole}} \right| = \underline{\underline{37.4 \text{ lb}_m}}$$

Ideal gas gives a conservative estimate. It calls for charging less O_2 than the tank can safely hold.

- c.
1. Pressure gauge is faulty
 2. The room temperature is higher than 50°F
 3. Crack or weakness in the tank
 4. Tank was not completely evacuated before charging and O_2 reacted with something in the tank
 5. Faulty scale used to measure O_2
 6. The tank was mislabeled and did not contain pure oxygen.

5.63 a. SRK Equation of State:
$$P = \frac{RT}{(\hat{V} - b)} - \frac{\alpha a}{\hat{V}(\hat{V} + b)}$$

\Rightarrow multiply both sides of the equation by $\hat{V}(\hat{V} - b)(\hat{V} + b)$:

$$f(\hat{V}) = P\hat{V}(\hat{V} - b)(\hat{V} + b) - RT\hat{V}(\hat{V} + b) + \alpha a(\hat{V} - b) = 0$$

$$f(\hat{V}) = P\hat{V}^3 - RT\hat{V}^2 + (\alpha a - b^2P - bRT)\hat{V} - \alpha ab = 0$$

6.9 a. $m = 2 \quad \pi = 2 \Rightarrow \underline{F = 2 + 2 - 2 = 2}$. Two intensive variable values (e.g., T & P) must be specified to determine the state of the system.

b. $\log p^*_{MEK} = 6.97421 - \frac{1209.6}{55 + 216} = 2.5107 \Rightarrow p^*_{MEK} = 10^{2.5107} = 324 \text{ mm Hg}$

Since vapor & liquid are in equilibrium $p_{MEK} = p^*_{MEK} = \underline{324 \text{ mm Hg}}$

$\Rightarrow y_{MEK} = p_{MEK} / P = 324/1200 = \underline{0.27} > 0.115$ The vessel does not constitute an explosion hazard.

6.10 a. The solvent with the lower flash point is easier to ignite and more dangerous. The solvent with a flash point of 15°C should always be prevented from contacting air at room temperature. The other one should be kept from any heating sources when contacted with air.

b. At the LFL, $y_M = 0.06 \Rightarrow p_M = p^*_M = 0.06 \times 760 \text{ mm Hg} = 45.60 \text{ mm Hg}$

Antoine $\Rightarrow \log_{10} 45.60 = 7.87863 - \frac{1473.11}{T + 230} \Rightarrow T = \underline{6.85^\circ \text{C}}$

c. The flame may heat up the methanol-air mixture, raising its temperature above the flash point.

6.11 a. At the dew point,

Increase in $T \Rightarrow$ increase in $V \Rightarrow$ decrease in density

Increase in $h_r \Rightarrow$ more water (MW = 18), less dry air (MW = 29)

\Rightarrow decrease in $m \Rightarrow$ decrease in density

Since the density in hot, humid air is lower than in cooler, dryer air, the buoyancy force on the ball must also be lower. Therefore, the statement is wrong.

- 6.24 a. Maximum mole fraction of nonane achieved if all the liquid evaporates and none escapes.

$$n_{\max} = \frac{15 \text{ L C}_9\text{H}_{20} (l) \quad \swarrow (SG)_{\text{nonane}} \quad 0.718 \times 1.00 \text{ kg}}{\text{L C}_9\text{H}_{20} \quad 128.25 \text{ kg}} \times \frac{\text{kmol}}{128.25 \text{ kg}} = 0.084 \text{ kmol C}_9\text{H}_{20}$$

Assume $T = 25^\circ \text{C}$, $P = 1 \text{ atm}$

$$n_{\text{gas}} = \frac{2 \times 10^4 \text{ L} \quad 273 \text{ K}}{298 \text{ K}} \times \frac{1 \text{ kmol}}{22.4 \times 10^3 \text{ L(STP)}} = 0.818 \text{ kmol}$$

$$y_{\max} = \frac{n_{\max}}{n_{\text{gas}}} = \frac{0.084 \text{ kmol C}_9\text{H}_{20}}{0.818 \text{ kmol}} = 0.10 \text{ kmol C}_9\text{H}_{20} / \text{kmol (10 mole\%)}$$

As the nonane evaporates, the mole fraction will pass through the explosive range (0.8% to 2.9%). The answer is therefore yes.

The nonane will not spread uniformly—it will be high near the sump as long as liquid is present (and low far from the sump). There will always be a region where the mixture is explosive at some time during the evaporation.

$$\text{b. } \ln p^* = -\frac{A}{T} + B \quad T_1 = 25.8^\circ \text{C} = 299 \text{ K}, p_1^* = 5.00 \text{ mmHg}$$

- c. The purpose of purge is to evaporate and carry out the liquid nonane. Using steam rather than air is to make sure an explosive mixture of nonane and oxygen is never present in the tank. Before anyone goes into the tank, a sample of the contents should be drawn and analyzed for nonane.

Although the problem does not call for it, we could also calculate that $n_2 = 375 \text{ mol exhaled/day}$, $y_2 = 0.0619$, and the rate of weight loss by breathing at 23°C and 50% relative humidity is
 $n_0(18) = (n_2 y_2 - n_1 y_1)18 = 329 \text{ g/day}$.

$$\log_{10} p_A^*(20^\circ\text{C}) = 7.11714 - \frac{1210.595}{20 + 229.664} = 2.26824 \Rightarrow p_A^*(20^\circ\text{C}) = 184.6 \text{ mmHg}$$

Saturation: $y_1 \cdot P = p_A^*(20^\circ\text{C}) \Rightarrow y_1 = \frac{184.6}{760} = 0.243 > 0.2$, so no saturation occurs.

For refrigerant at -35°C

- c. When T_f decreases, P_f decreases. Decreasing temperature and increasing pressure both to increase the fractional condensation. When you decrease T_f , less compression is required to achieve a specified fractional condensation.
- d. A lower T_f requires more refrigeration and therefore a greater refrigeration cost (C_{refr}). However, since less compression is required at the lower temperature, C_{comp} is lower at the lower temperature. Similarly, running at a higher T_f lowers the refrigeration cost but raises the compression cost. The sum of the two costs is a minimum at an intermediate temperature.

- e. If the column is long enough, the liquid flowing down eventually approaches equilibrium with the entering gas. At 70°C, the mole fraction of hexane in the exiting liquid in equilibrium with the mole fraction in the entering gas is 4.56×10^{-4} mol H/mol, which is insufficient to bring the total hexane absorption to the desired level. To reach that level at 70°C, either the liquid feed rate must be increased or the pressure must be raised to a value for which the final mole fraction of hexane in the vapor is 2.63×10^{-4} or less. (To be more precise, we could convert the given mole fractions to mass fractions and calculate the weighted average density of the mixture, but since the pure component densities are almost identical there is little point in doing all that.)

$M_A = 58.08 \text{ g/mol}$, $M_E = 46.07 \text{ g/mol}$

$\Rightarrow M_l = (0.34)(58.08) + (1 - 0.34)(46.07) = 50.15 \text{ g/mol}$

Basis: 1 mol liquid $\Rightarrow (0.762 \text{ mol vapor} / 0.238 \text{ mol liquid}) = 3.2 \text{ mol vapor}$

Liquid volume: $V_l = \frac{(1 \text{ mol})(50.15 \text{ g/mol})}{(0.790 \text{ g/cm}^3)} = 63.48 \text{ cm}^3$

We assume (1) the validity of Antoine's equation and Raoult's law, (ii) that pressure head and surface tension effects on the boiling point are negligible.

The liquid temperature will rise until it reaches 79.9°C , where boiling will commence. The escaping vapor will be richer in methanol and thus the liquid composition will become richer in propanol. The increasing fraction of the less volatile component in the residual liquid will cause the boiling temperature to rise.

Strategy

- Calculate molar flow rate of product (\dot{n}_p) from mass flow rate and composition
- Calculate y_{A3} and y_{E3} from Raoult's law: $y_{H3} = 1 - y_{A3} - y_{E3}$. Balances about the still involve fewest unknowns (\dot{n}_c and \dot{n}_r)
- Total mole balance about still
A balance about still $\Rightarrow \dot{n}_c, \dot{n}_r$
- A, E and H_2 balances about scrubber $\Rightarrow \dot{n}_{A4}, \dot{n}_{E4}$, and \dot{n}_{H4} in terms of \dot{n}_3 . Overall atomic balances on C, H, and O now involve only 2 unknowns (\dot{n}_0, \dot{n}_3)
- Overall C balance
Overall H balance $\Rightarrow \dot{n}_0, \dot{n}_3$
- A balance about fresh feed-recycle mixing point $\Rightarrow \dot{n}_{A1}$
- E balance about fresh feed-recycle mixing point $\Rightarrow \dot{n}_{E1}$
- A, E, H_2 balances about condenser $\dot{n}_{A2}, \dot{n}_{E2}, \dot{n}_{H2}$
- All desired quantities may now be calculated from known molar flow rates.

(c) Liquid feed: $(100)(56.39) = \underline{\underline{5640 \text{ kg/h}}}$

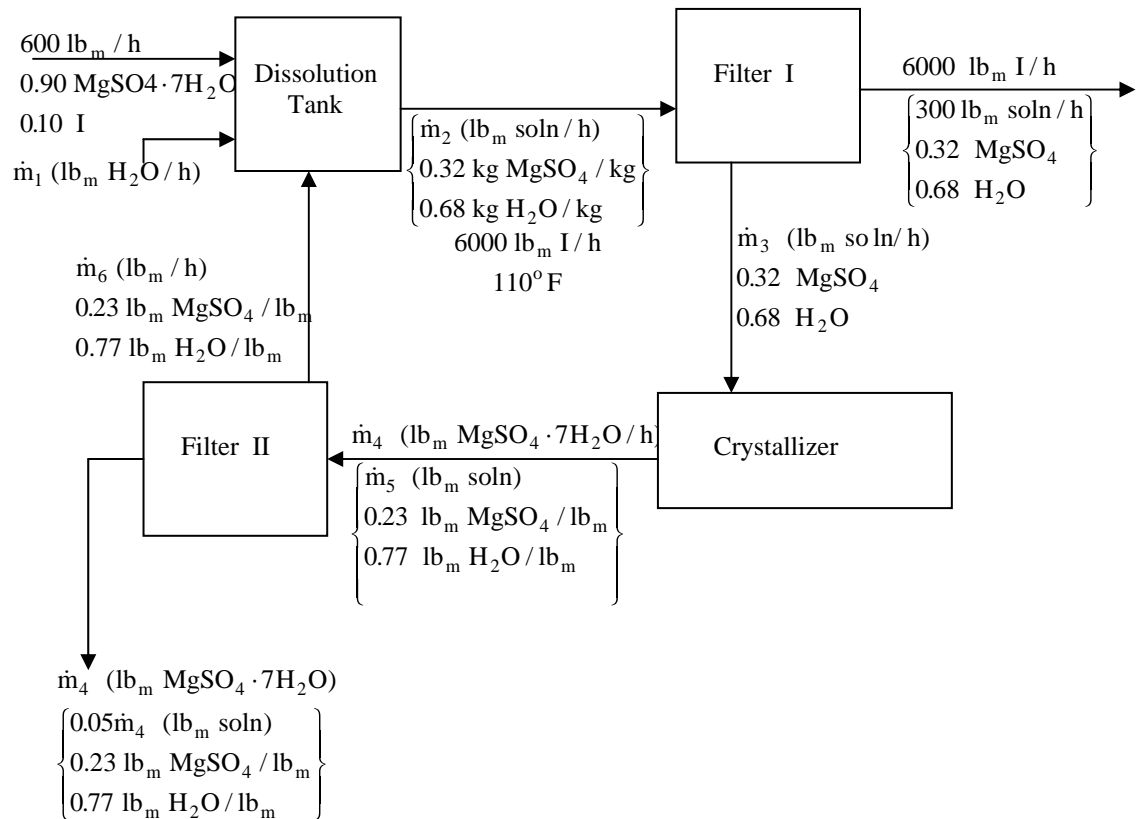

To calculate \dot{V} , we would need to know the density of a 7 wt% aqueous Na_2CO_3 solution.

(d) If T dropped in the filter, more solid NaHCO_3 would be recovered and the residual solution would contain less than 2.4% NaHCO_3 .

(e)

Benefit: Higher pressure \Rightarrow greater $p_{\text{CO}_2} \xRightarrow{\text{Henry's law}}$ higher concentration of CO_2 in solution
 \Rightarrow higher rate of reaction \Rightarrow smaller reactor needed to get the same conversion \Rightarrow lower cost
Penalty: Higher pressure \Rightarrow greater cost of compressing the gas (purchase cost of compressor, power consumption)

- c.** (i). The first transfer (low pH) separates most of the P from the other broth constituents, which are not soluble in butyl acetate. The second transfer (high pH) moves the penicillin back into an aqueous phase without the broth impurities.

Overall: $T_{\text{initial}} = T_{\text{final}} \Rightarrow \Delta U = 0 \Rightarrow \underline{\underline{Q - W = 0}}$

In step 1, the gas expands $\Rightarrow W > 0 \Rightarrow \Delta U < 0 \Rightarrow \underline{\underline{T \text{ decreases}}}$

(c) Downward force $F_d = (1.00)(1.01325 \times 10^5)(2.83 \times 10^{-3}) + (4.50)(9.81)(1) = 331 \text{ N}$ (units as in Part (a))

Final gas pressure $P_f = \frac{F}{A} = \frac{331 \text{ N}}{2.83 \times 10^{-3} \text{ m}^2} = 1.16 \times 10^5 \text{ N/m}^2$

Since $T_0 = T_f = 30^\circ \text{C}$, $P_f V_f = P_0 V_0 \Rightarrow V_f = V_0 \frac{P_0}{P_f} = (0.677 \text{ L}) \frac{1.86 \times 10^5 \text{ Pa}}{1.16 \times 10^5 \text{ Pa}} = 1.08 \text{ L}$

Distance traversed by piston $= \frac{\Delta V}{A} = \frac{(1.08 - 0.677) \text{ L}}{10^3 \text{ L}} \left| \frac{1 \text{ m}^3}{10^3 \text{ L}} \right| \left| \frac{1}{2.83 \times 10^{-3} \text{ m}^2} \right| = 0.142 \text{ m}$

$$\Rightarrow W = Fd = (331 \text{ N})(0.142 \text{ m}) = 47 \text{ N} \cdot \text{m} = 47 \text{ J}$$

Since work is done by the gas on its surroundings, $W = +47 \text{ J} \xRightarrow{Q-W=0} \underline{\underline{Q = +47 \text{ J}}}$

The calculation in (b) is more accurate because the steam tables account for the effect of pressure on specific enthalpy (nonideal gas behavior).

(d) Most energy released goes to raise the temperature of the combustion products, some is transferred to the boiler tubes and walls, and some is lost to the surroundings.

$$\dot{Q} = \dot{Q}_{\text{evaporator}} - \dot{Q}_{\text{condenser}} = 2000 - 2500 = -500 \text{ Btu/min}$$

and the compressor work \dot{W}_c represents the total work done on the system. The system is closed (no mass flow in or out). Consider a time interval Δt (min). Since the system is at steady state, the changes ΔU , ΔE_k and ΔE_p over this time interval all equal zero. The total heat input is $\dot{Q}\Delta t$, the work input is $\dot{W}_c\Delta t$, and (Eq. 8.3-4) yields

$$\dot{Q}\Delta t - \dot{W}_c\Delta t = 0 \Rightarrow \dot{W}_c = \dot{Q} = \frac{-500 \text{ Btu}}{\text{min}} \left| \frac{1 \text{ min}}{60 \text{ s}} \right| \left| \frac{1.341 \times 10^{-3} \text{ hp}}{9.486 \times 10^{-4} \text{ Btu/s}} \right| = \underline{\underline{11.8 \text{ hp}}}$$

Antoine Equation. For $T = 90^\circ\text{C}$ and $P = 652 \text{ mmHg}$:

$$P_B^*(90^\circ\text{C}) = 10^{[6.89272 - 1203.531 / (90 + 219.888)]} = 1021 \text{ mmHg}$$

$$P_T^*(90^\circ\text{C}) = 10^{[6.95805 - 1346.773 / (90 + 219.693)]} = 406.7 \text{ mmHg}$$

Adding equations (8) and (9) \Rightarrow

$$P = x_B P_B^* + (1 - x_B) P_T^* \Rightarrow x_B = \frac{P - P_T^*}{P_B^* - P_T^*} = \frac{P - P_T^*}{P_B^* - P_T^*} = \frac{652 - 406.7}{1021 - 406.7} = 0.399 \text{ mol B(l) / mol}$$

$$y_B = \frac{x_B P_B^*}{P} = \frac{0.399(1021 \text{ mmHg})}{652 \text{ mmHg}} = 0.625 \text{ mol B(v) / mol}$$

$$\text{Solving (1) and (2)} \Rightarrow n_V = \frac{z_B - x_B}{y_B - x_B} = \frac{0.5 - 0.399}{0.625 - 0.399} = 0.446 \text{ mol vapor}$$

$$n_L = 1 - n_V = 1 - 0.446 = 0.554 \text{ mol liquid}$$

(c). If $P < P_{\min}$, all the output is vapor. If $P > P_{\max}$, all the output is liquid.

(d) At $P=652$ mmHg it is necessary to add heat to achieve the equilibrium and at $P=714$ mmHg, it is necessary to release heat to achieve the equilibrium. The higher the pressure, there is more liquid than vapor, and the liquid has a lower enthalpy than the equilibrium vapor: enthalpy out < enthalpy in.

The first value uses physical properties of water at 1 atm (Tables B.1, B.2, and B.8), while the heat of vaporization at 50°C in Table B.5 is for a pressure of 0.1234 bar (0.12 atm). The difference is ΔH for liquid water going from 50°C and 0.1234 bar to 50°C and 1 atm plus ΔH for water vapor going from 50°C and 1 atm to 50°C and 0.1234 bar.

- e. In an adiabatic system, when a liquid evaporates, the temperature of the remaining condensed phase drops. In this problem, the heat transferred from the air goes to (1) vaporize 90% of the acetone in the feed; (2) raise the temperature of the remaining wet film above what it would be if the process were adiabatic. If the feed air temperature is above about 530°C , enough heat is transferred to keep the film above its inlet temperature of 35°C ; otherwise, the film temperature drops.

- e. The heat loss leads to a pumping cost for the additional heating fluid and a greater heating cost to raise the additional fluid back to 215°C.
- f. Adding the insulation reduces the costs given in part (e). The insulation is probably preferable since it is a one-time cost and the other costs continue as long as the process runs. The final decision would depend on how long it would take for the savings to make up for the cost of buying and installing the insulation.

$$\Delta \hat{H}_r^\circ = -904.7 \text{ kJ/mol}$$

- a. When 4 g-moles of $\text{NH}_3(\text{g})$ and 5 g-moles of $\text{O}_2(\text{g})$ at 25°C and 1 atm react to form 4 g-moles of $\text{NO}(\text{g})$ and 6 g-moles of water vapor at 25°C and 1 atm, the change in enthalpy is -904.7 kJ.
- b. Exothermic at 25°C . The reactor must be cooled to keep the temperature constant. The temperature would increase under adiabatic conditions. The energy required to break the molecular bonds of the reactants is less than the energy released when the product bonds are formed.

Reducing the stoichiometric coefficients of a reaction by half reduces the heat of reaction by half.

$$\Delta \hat{H}_r^\circ = -\frac{904.7}{2} = \underline{\underline{-452.4 \text{ kJ/mol}}}$$

Reversing the reaction reverses the sign of the heat of reaction. Also reducing the stoichiometric coefficients to one-fourth reduces the heat of reaction to one-fourth.

$$\Delta \hat{H}_r^\circ = -\frac{(-904.7)}{4} = \underline{\underline{+226.2 \text{ kJ/mol}}}$$

Benefits

Preheating CO \Rightarrow more heat transferred from reactor (possibly generate additional steam for plant)

Cooling CO \Rightarrow lower cooling cost in condenser.

b.

Advantages of CO. Gases are easier to store and transport than solids, and the product of the combustion is CO₂, which is a much lower environmental hazard than are the products of coke combustion.

Disadvantages of CO. It is highly toxic and dangerous if it leaks or is not completely burned, and it has a lower heating value than coke. Also, it costs something to produce it from coke.

- c. The energy balance on the furnace includes the term $-\sum n_{\text{in}} \hat{H}_{\text{in}}$. If the air is preheated and the stack gas temperature remains the same, this term and hence \dot{Q} become more negative, meaning that more heat is transferred to the boiler water and more steam is produced. The stack gas is a logical heating medium since it is available at a high temperature and costs nothing.

This yield is $(1 \text{ mol C}_2\text{H}_2/2 \text{ mol CH}_4) = 0.500 \text{ mol C}_2\text{H}_2/2 \text{ mol CH}_4$.

The ratio of the actual yield to the theoretical yield is $0.154/0.500 = \underline{\underline{0.308}}$.

- b. Cost of fuel oil, natural gas, fuel oil and air preheating, pumping and compression, piping, utilities, operating personnel, instrumentation and control, environmental monitoring. Lowering environmental hazard might justify lack of profit.
- c. Put hot product gases from boiler and/or incinerator through heat exchangers to preheat both air streams. Make use of steam from dryer.
- d. Sulfur dioxide, possibly NO₂, fly ash in boiler stack gas, volatile toxic and odorous compounds in gas effluents from dryer and incinerator.

CHAPTER TEN

10.1 b. Assume no combustion

11 variables $(n_1, n_2, n_3, x_1, x_2, y_1, y_2, y_3, T_1, T_2, Q)$
 -5 relations (4 material balances and 1 energy balance)
 6 degrees of freedom

A feasible set of design variables: $\{n_1, n_2, x_1, x_2, T_1, T_2\}$

Calculate n_3 from total mole balance, y_1, y_2 , and y_3 from component balances, Q from energy balance.

An infeasible set: $\{n_1, n_2, n_3, x_1, x_2, T_1\}$

Specifying n_1 and n_2 determines n_3 (from a total mole balance)

c.

9 variables $(n_1, n_2, n_3, y_1, y_2, T_1, T_2, Q, P)$
 -4 relations (2 material, 1 energy, and 1 equilibrium: $y_2 P = P_{C_6H_{14}}^*(T_2)$)
 5 degrees of freedom

A feasible set: $\{n, y_1, T_1, P, n_3\}$

Calculate n_2 from total balance, y_2 from C_6H_{14} balance, T_2 from Raoult's law:
 $[y_2 P = P_{C_6H_{14}}^*(T_2)]$, Q from energy balance

An infeasible set: $\{n_2, y_2, n_3, P, T_2\}$

Once y_2 and P are specified, T_2 is determined from Raoult's law

10.2 10 variables $(n_1, n_2, n_3, n_4, x_1, x_2, x_3, x_4, T, P)$

–2 material balances

–2 equilibrium relations: $[x_3 P = x_4 P_B^*(T), (1 - x_3)P = (1 - x_4)P_C^*(T)]$

6 degrees of freedom

a. A straightforward set: $\{n_1, n_3, n_4, x_1, x_4, T\}$

Calculate n_2 from total material balance, P from sum of Raoult's laws:

$$P = x_4 P_B^*(T) + (1 - x_4)P_C^*(T)$$

x_3 from Raoult's law, x_2 from B balance

b. An iterative set: $\{n_1, n_2, n_3, x_1, x_2, x_3\}$

Calculate n_4 from total mole balance, x_4 from B balance.

Guess P , calculate T from Raoult's law for B , P from Raoult's law for C , iterate until pressure checks.

c. An impossible set: $\{n_1, n_2, n_3, n_4, T, P\}$

Once n_1, n_2 , and n_3 are specified, a total mole balance determines n_4 .

10.3 $2\text{BaSO}_4(\text{s}) + 4\text{C}(\text{s}) \rightarrow 2\text{BaS}(\text{s}) + 4\text{CO}_2(\text{g})$

11 variables $(n_0, n_1, n_2, n_3, n_4, x_b, x_c, T_0, T_f, Q, P_{\text{ex}})$

–5 material balances (C, BaS, CO_2 , BaSO_4 , other solids)

–1 energy balance

+1 reaction

–1 relation defining P_{ex} in terms of n_0, x_b , and x_c

5 degrees of freedom

b. Design set: $\{x_b, x_c, T_0, T_f, P_{\text{ex}}\}$

Calculate n_0 from x_b, x_c , and P_{ex} ; n_1 through n_4 from material balances,

Q from energy balance

10.3 (cont'd)

c. Design set: $\{x_B, x_c, T_0, n_2, Q\}$

Specifying x_B determines $n_2 \Rightarrow$ impossible design set.

d. Design set: $\{x_B, x_c, T_0, P_{ex}, Q\}$

Calculate n_2 from x_B , n_3 from x_B

n_0 from x_B, x_c and P_{ex}

n_1 from C material balance, n_4 from total material balance

T_f from energy balance (trial-and-error probably required)

a. 13 variables $(n_f, n_{aw}, n_e, n_{eh}, n_{ea}, n_w, n_{ex}, n_0, x_{ef}, T_0, T, Q, P_{xs})$

–6 material balances

–1 energy balance

–1 relation between P_{xs}, n_f, x_{ef} , and n_{air}

+2 reactions

7 degrees of freedom

b. Design set: $\{n_f, x_{ef}, P_{xs}, n_e, n_{ah}, T_0, T\}$

Calculate n_{air} from n_f, x_{ef} and P_{xs} ; n_n from N_2 balance;

n_{aa} and n_w from n_f, x_{ef}, n_e, n_{ah} and material balances;

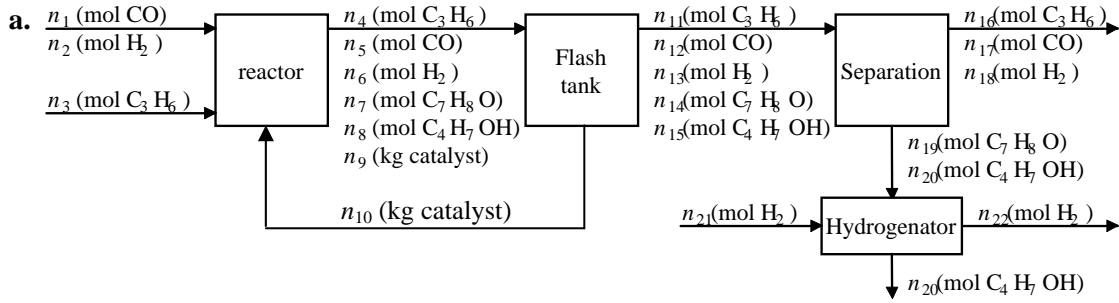

n_{ex} from O atomic balance; Q from energy balance

c. Design set: $\{n_f, x_{ef}, T_0, n_{air}, Q, n_e, n_w\}$

Calculate P_{xs} from n_f, x_{ef} and n_{air} ; n 's from material balances; T from energy balance (generally nonlinear in T)

d. Design set: $\{n_{air}, n_n, \dots\}$. Once n_{air} is specified, an N_2 balance fixes n_n

10.5

Reactor: 10 variables ($n_1 - n_{16}$)
 -6 material balances
 +2 reactions

 6 degrees of freedom

Flash Tank: 12 variables ($n_4 - n_{15}$)
 -6 material balances

 6 degrees of freedom

Separation: 10 variables ($n_{11} - n_{20}$)
 -5 material balances

 5 degrees of freedom

Hydrogenator: 5 variables ($n_{19} - n_{23}$)
 -3 material balances
 +1 reaction

 3 degrees of freedom

Process: 20 Local degrees of freedom
 -14 ties

 6 overall degrees of freedom

The last answer is what one gets by observing that 14 variables were counted two times each in summing the local degrees of freedom. However, one relation also was counted twice: the catalyst material balances on the reactor and flash tank are each $n_9 = n_{10}$. We must therefore add one degree of freedom to compensate for having subtracted the same relation twice, to finally obtain 7 overall degrees of freedom (A student who gets this one has done very well indeed!)

- b. The catalyst circulation rate is not included in any equations other than the catalyst balance ($n_9 = n_{10}$). It may therefore not be determined unless either n_9 or n_{10} is specified.

10.6 $n - C_4H_{10} \rightarrow i - C_4H_{10} \quad (n - B = i - B)$

a. Mixer: 5 variables (n_1, n_2, n_3, n_r, x_r)
 -2 material balances

 3 degrees of freedom

Reactor: 4 variables (n_2, n_3, n_4, n_5)
 -2 material balances
 +1 reaction

 3 degrees of freedom

Still: 6 variables ($n_4, n_5, n_6, x_6, n_r, x_r$)
 -2 material balances

 4 degrees of freedom

Process: 10 Local degrees of freedom
 - 6 ties

 4 overall degrees of freedom

b. $n_1 = 100 \text{ mol } n - C_4H_{10}, x_6 = 0.115 \text{ mol } n - C_4H_{10}/\text{mol}, x_r = 0.85 \text{ mol } n - C_4H_{10}/\text{mol}$

Overall C balance: $(100)(4) = n_6[(0.115)(4) + (0.885)(4)] \text{ mol C} \Rightarrow n_6 = 100 \text{ mol overhead}$

Overall conversion $= \frac{100 \text{ mol } n - B \text{ fed} - (100)(0.115) \text{ mol } n - B \text{ unreacted}}{100 \text{ mol } n - B \text{ fed}} \times 100\% = \underline{\underline{88.5\%}}$

Mixer n-B balance: $100 + 0.85n_r = n_2 \quad (1)$

35% S.P. conversion: $n_4 = 0.65n_2 \Rightarrow n_4 = 65 + 0.5525n_r \quad (2)$

Still n - B balance:

$n_4 = n_6x_6 + n_rx_r \Rightarrow 65 + 0.5525n_r = (0.115)(100) + 0.85n_r \Rightarrow n_r = 179.83 \text{ mol}$

Recycle ratio $= (179.83 \text{ mol recycle}) / (100 \text{ mol fresh feed}) = 1.79 \frac{\text{mol recycle}}{\text{mol fresh feed}}$

Antoine equations: $\underline{p_{Bz}^*} = 10^{6.89272 - 1211.033 / (T + 220.790)} (=1350.491)$

$\underline{p_{Tl}^*} = 10^{6.95805 - 1346.773 / (T + 219.693)} (=556.3212)$

Raoult's law: $\underline{x_{Bz}} = (P - p_{Tl}^*) / (p_{Bz}^* - p_{Tl}^*) (=0.307)$, $\underline{y_{Bz}} = x_{Bz} p_{Bz}^* / P (=0.518)$

Total mole balance: $100 = n_v + n_l$

Benzene balance: $40 = y_{Bz} n_v + x_{Bz} n_l$

$$\Rightarrow \underline{n_v} = \frac{40 - 100 x_{Bz}}{y_{Bz} - x_{Bz}} (=44.13), \underline{n_l} = 100 - n_v (=55.87)$$

Given \dot{n}_F and x_F (or \dot{n}_{AF} and \dot{n}_{BF}), T_F, P, y_c (fractional condensation),

Fractional condensation $\Rightarrow \underline{\dot{n}_l} = y_c \dot{n}_F x_F$

Mole balance $\Rightarrow \underline{\dot{n}_v} = \dot{n}_F - \dot{n}_l$

A balance $\Rightarrow \underline{x_v} = (\dot{n}_F x_F - \dot{n}_l) / \dot{n}_v$

Raoult's law $\Rightarrow \underline{p_A^*} = x_v P$

Antoine's equation $\Rightarrow \underline{T} = \frac{B}{A - \log_{10} p_A^*} - C$

Enthalpies: $\underline{\hat{H}_1} = \Delta \hat{H}_v + C_{pv} (T_F - 25), \underline{\hat{H}_2} = C_{pg} (T_F - 25), \underline{\hat{H}_3} = C_{pl} (T - 25),$

$\underline{\hat{H}_4} = \Delta \hat{H}_v + C_{pv} (T - 25), \underline{\hat{H}_5} = C_{pg} (T - 25)$

Energy balance: $\underline{\dot{Q}} = \sum \dot{n}_{out} \hat{H}_{out} - \sum \dot{n}_{in} \hat{H}_{in}$

The second reaction consumes six times more oxygen per mole of ethylene consumed. The lower the single pass ethylene oxide yield, the more oxygen is consumed in the second reaction. At a certain yield for a specified ethylene conversion, all the oxygen in the feed is consumed. A yield lower than this value would be physically impossible.

CHAPTER ELEVEN

- 11.1 a.** The peroxide mass fraction in the effluent liquid equals that in the tank contents, which is:

$$x_p = \frac{M_p}{M}$$

Therefore, the leakage rate of hydrogen peroxide is $\dot{m}_l M_p / M$

- b.** Balance on mass: Accumulation = input – output

⇓

$$\frac{dM}{dt} = \dot{m}_0 - \dot{m}_l$$

$$t = 0, M = M_0 \text{ (mass in tank when leakage begins)}$$

Balance on H_2O_2 : Accumulation = input – output – consumption

⇓

$$\frac{dM_p}{dt} = \dot{m}_0 x_{p0} - \dot{m}_l \left(\frac{M_p}{M} \right) - k M_p$$

$$t = 0, M_p = M_{p0}$$

- 11.2 a.** Balance on H_3PO_4 : Accumulation = input

Density of H_3PO_4 : $\rho = 1.834 \text{ g / ml}$.

Molecular weight of H_3PO_4 : $M = 98.00 \text{ g / mol}$.

$$\text{Accumulation} = \frac{dn_p}{dt} \text{ (kmol / min)}$$

$$\text{Input} = \frac{20.0 \text{ L}}{\text{min}} \times \frac{1000 \text{ ml}}{\text{L}} \times \frac{1.834 \text{ g}}{\text{ml}} \times \frac{\text{mol}}{98.00 \text{ g}} \times \frac{1 \text{ kmol}}{1000 \text{ mol}} = 0.3743 \text{ kmol / min}$$

⇓

$$\frac{dn_p}{dt} = 0.3743$$

$$t = 0, n_{p0} = 150 \times 0.05 = 7.5 \text{ kmol}$$

b. $\int_{7.5}^{n_p} dn_p = \int_0^t 0.3743 dt \Rightarrow n_p = 7.5 + 0.3743t \text{ (kmol } H_3PO_4 \text{ in tank)}$

$$x_p = \frac{n_p}{n} = \frac{n_p}{n_0 + n_p - n_{p0}} = \frac{7.5 + 0.3743t}{150 + 0.3743t} \frac{\text{kmol } H_3PO_4}{\text{kmol}}$$

c. $0.15 = \frac{7.5 + 0.3743t}{150 + 0.3743t} \Rightarrow t = 47.1 \text{ min}$

11.3 a. $\dot{m}_w = a + bt$ ($t = 0, \dot{m}_w = 750$) & ($t = 5, \dot{m}_w = 1000$) $\Rightarrow \dot{m}_w (\text{kg/h}) = 750 + 50t$ (h)

Balance on methanol: Accumulation = Input – Output

$M = \text{kg CH}_3\text{OH in tank}$

$$\frac{dM}{dt} = \dot{m}_f - \dot{m}_w = 1200 \text{ kg/h} - (750 + 50t) \text{ kg/h}$$

\Downarrow

$$\frac{dM}{dt} = 450 - 50t (\text{kg/h})$$

$$t = 0, M = 750 \text{ kg}$$

b. $\int_{750}^M dM = \int_0^t (450 - 50t) dt$

\Downarrow

$$M - 750 = 450t - 25t^2$$

\Downarrow

$$\underline{\underline{M = 750 + 450t - 25t^2}}$$

Check the solution in two ways:

(1) $t = 0, M = 750 \text{ kg} \Rightarrow$ satisfies the initial condition;

(2) $\frac{dM}{dt} = 450 - 50t \Rightarrow$ reproduces the mass balance.

c. $\frac{dM}{dt} = 0 \Rightarrow t = 450/50 = \underline{\underline{9 \text{ h}}} \Rightarrow M = 750 + 450(9) - 25(9)^2 = \underline{\underline{2775 \text{ kg}}}$ (maximum)

$$M = 0 = 750 + 450t - 25t^2$$

$$t = \frac{-450 \pm \sqrt{(450)^2 + 4(25)(750)}}{2(-25)} \Rightarrow t = \cancel{1.54 \text{ h}}, \underline{\underline{19.54 \text{ h}}}$$

d. $\frac{3.40 \text{ m}^3}{1 \text{ m}^3} \left| \frac{10^3 \text{ liter}}{1 \text{ liter}} \right| \frac{0.792 \text{ kg}}{1 \text{ liter}} = 2693 \text{ kg}$ (capacity of tank)

$$M = 2693 = 750 + 450t - 25t^2$$

$$t = \frac{-450 \pm \sqrt{(450)^2 + 4(25)(750 - 2693)}}{2(-25)} \Rightarrow t = 7.19 \text{ h}, 10.81 \text{ h}$$

Expressions for $M(t)$ are:

$$M(t) = \begin{cases} 750 + 450t - 25t^2 & (0 \leq t \leq 7.19 \text{ and } 10.81 \leq t \leq 19.54) \text{ (tank is filling or draining)} \\ 2693 & (7.19 \leq t \leq 10.81) \text{ (tank is overflowing)} \\ 0 & (19.54 \leq t \leq 20.54) \text{ (tank is empty, draining)} \end{cases}$$

b. Balance on air in tank: Accumulation = input

$$\underline{\underline{\frac{dN}{dt} = 0.0117 (\text{lb - moles/s}); t = 0, N = 0.0258 \text{ lb - mole}}}$$

c. Integrate balance: $\int_{0.0258}^N dN = \int_0^t \dot{n} dt \Rightarrow \underline{\underline{N = 0.0258 + 0.0117t (\text{lb - mole air})}}$

Check the solution in two ways:

(1) $t = 0, N = 0.0258 \text{ lb - mole} \Rightarrow$ satisfies the initial condition

(2) $\frac{dN}{dt} = 0.0117 \text{ lb - mole air / s} \Rightarrow$ reproduces the mass balance

d. $t = 120 \text{ s} \Rightarrow N = 0.0258 + (0.0117)(120) = 1.43 \text{ lb - moles air}$

(Balance volume directly since density is constant)

$$\underline{\underline{\frac{dV}{dt} = 20.0 - 0.200V}} \\ \underline{\underline{t = 0, V = 300}}$$

$$\text{c.} \quad \frac{dV}{dt} = 0 = 20.0 - 0.200V_s \Rightarrow \underline{\underline{V_s = 100 \text{ L}}}$$

The plot of V vs. t begins at (t=0, V=300). When t=0, the slope (dV/dt) is $20.0 - 0.200(300) = -40.0$. As t increases, V decreases. $\Rightarrow dV/dt = 20.0 - 0.200V$ becomes less negative, approaches zero as $t \rightarrow \infty$. The curve is therefore concave up.

$$\ln D = bt + \ln a \Leftrightarrow D = ae^{bt}$$

$$b = \frac{\ln D_2/D_1}{t_2 - t_1} = \frac{\ln(755/2385)}{6 - 1} = -0.230$$

$$\ln a = \ln D_1 - bt_1 = \ln(2385) + (0.230)(1) = 8.007 \Rightarrow a = e^{8.007} = 3000$$

$N=45,440$
 $\dot{n}=28,920$

$$t = 0, x = \frac{1.5 \text{ mol SO}_2}{45,440 \text{ mol}} = 3.30 \times 10^{-5} \text{ mol SO}_2/\text{mol}$$

- b.** The plot of x vs. t begins at ($t=0$, $x=3.30 \times 10^{-5}$). When $t=0$, the slope (dx/dt) is $-0.6364 \times 3.30 \times 10^{-5} = -2.10 \times 10^{-5}$. As t increases, x decreases. \Rightarrow $dx/dt = -0.6364x$ becomes less negative, approaches zero as $t \rightarrow \infty$. The curve is therefore concave up.

11.8 (cont'd)

- c. Separate variables and integrate the balance equation:

$$\int_{3.30 \times 10^{-5}}^x \frac{dx}{x} = \int_0^t -0.6364 dt \Rightarrow \ln \frac{x}{3.30 \times 10^{-5}} = -0.6364t \Rightarrow \underline{\underline{x = 3.30 \times 10^{-5} e^{-0.6364t}}}$$

Check the solution in two ways:

- (1) $t = 0$, $x = 3.30 \times 10^{-5}$ mol SO₂ / mol \Rightarrow satisfies the initial condition;
 (2) $\frac{dx}{dt} = -0.6364 \times 3.30 \times 10^{-5} e^{-0.6364t} = -0.6364x \Rightarrow$ reproduces the mass balance.

ii) $x = 10^{-6} \Rightarrow t = \frac{\ln(10^{-6} / 3.30 \times 10^{-5})}{-0.6364} = \underline{\underline{5.5 \text{ min}}}$

- e. The room air composition may not be uniform, so the actual concentration of the SO₂ in parts of the room may still be higher than the safe level. Also, “safe” is on the average; someone would be particularly sensitive to SO₂.

11.9 a. Balance on CO: Accumulation = -output

N (mol) x (mol CO / mol) = total moles of CO in the laboratory

Molar flow rate of entering and leaving gas: $\dot{n} \left(\frac{\text{kmol}}{\text{h}} \right) = \frac{P \dot{V}_p}{RT}$

CO balance: Accumulation = -output

11.19 (cont'd)

When the feed rate of A equals the rate at which A reacts, N_A reaches a steady value.

N_A would never reach the steady value in a real reactor. The reasons are:

(1) In our calculation, $V = \dot{v}t \Rightarrow t \rightarrow \infty, V \rightarrow \infty$.

But in a real reactor, the volume is limited by the reactor volume;

(2) The steady value can only be reached at $t \rightarrow \infty$. In a real reactor, the reaction time is finite.

$$\text{d. } \lim_{t \rightarrow \infty} C_A = \lim_{t \rightarrow \infty} \frac{C_{A0}[1 - \exp(-kt)]}{kt} = \lim_{t \rightarrow \infty} \frac{C_{A0}}{kt} = 0$$

c. $\int_{25}^{T_f} \frac{dT}{1.50 - 0.0224T} = \int_0^t dt \Rightarrow t = -\frac{1}{0.0224} \ln\left(\frac{1.50 - 0.0224T}{0.94}\right) \Rightarrow T = \frac{1.50 - 0.94 \exp(-0.0224t)}{0.0224}$

$$t = 40 \text{ min.} \Rightarrow \underline{\underline{T = 49.8^\circ\text{C}}}$$

d. U changed. Let $x = (UA)_{\text{new}}$. The differential equation becomes:

$$\frac{dT}{dt} = 0.3947 + 0.096x - (0.01579 + 5.721x)T$$

$$\int_{25}^{55} \frac{dT}{0.3947 + 0.096x - (0.01579 + 5.721 \times 10^{-4}x)T} = \int_0^{40} dt$$

$$\Rightarrow -\frac{1}{0.01579 + 5.721 \times 10^{-4}x} \ln \left[\frac{0.3947 + 0.096x - (0.01579 + 5.721 \times 10^{-4}x) \times 55}{0.3947 + 0.096x - (0.01579 + 5.721 \times 10^{-4}x) \times 25} \right] = 40$$

$$\Rightarrow x = 14.27 \text{ kJ / (min}\cdot^\circ\text{C)}$$

$$\frac{\Delta U}{U_{\text{initial}}} = \frac{\Delta(UA)}{(UA)_{\text{initial}}} = \frac{14.27 - 11.5}{11.5} \times 100\% = \underline{\underline{24.1\%}}$$

- b.** The benzene temperature will continue to rise until it reaches $T_b = 80.1^\circ\text{C}$; thereafter the heat input will serve to vaporize benzene isothermally.

Time to reach T_b (neglect evaporation): $t = \frac{80.1 - 20}{0.0649} = 926 \text{ s}$

Time remaining: 40 minutes (60 s/min) – 926 s = 1474 s

Evaporation: $\Delta\hat{H}_v = (30.765 \text{ kJ/mol})(1 \text{ mol}/78.11 \text{ g})(1000 \text{ J/kJ}) = 393 \text{ J/g}$

Evaporation rate = $(40.2 \text{ J/s}) / (393 \text{ J/g}) = 0.102 \text{ g/s}$

Benzene remaining = $350 \text{ g} - (0.102 \text{ g/s})(1474 \text{ s}) = \underline{\underline{200 \text{ g}}}$

 2. Put an open flask on the burner. Benzene vaporizes \Rightarrow toxicity, fire hazard.
Use a covered container or work under a hood.
 3. Left the burner unattended.
 4. Looked down into the flask with the boiling chemicals. Damage eyes. Wear goggles.
 5. Rubbed his eyes with his hand. Wash with water.
 6. Picked up flask with bare hands. Use lab gloves.
 7. Put hot flask on partner's homework. Fire hazard.

$$\underline{\underline{t = 0, T = 10^\circ\text{C}}}$$

(Note: a real process of this type would involve air escaping from the room and a constant pressure being maintained. We simplify the analysis by assuming n is constant.)

11.25 (cont'd)

b. At steady-state, $dT/dt = 0 \Rightarrow 40.3\dot{m}_s - 0.559T = 0 \Rightarrow \dot{m}_s = \frac{0.559T}{40.3}$
 $T = 24^\circ\text{C} \Rightarrow \underline{\underline{\dot{m}_s = 0.333 \text{ kg/hr}}}$

c. Separate variables and integrate the balance equation:

$$\int_{10}^{T_f} \frac{dT}{40.3\dot{m}_s - 0.559T} = \int_0^t dt \xrightarrow[\substack{\dot{m}_s = 0.333 \\ T_e = 23^\circ\text{C}}]{\substack{M = 250 \text{ kg} \\ C_v = 4.00 \text{ kJ/kg}\cdot^\circ\text{C}}} \int_{10}^{23} \frac{dT}{13.4 - 0.559T} = t$$

$$\Downarrow$$

$$t = -\frac{1}{0.559} \ln \left[\frac{13.4 - 0.559(23)}{13.4 - 0.559(10)} \right] = \underline{\underline{4.8 \text{ hr}}}$$

11.26 a. Integral energy balance ($t = 0$ to $t = 20$ min)

Required power input: $\dot{Q} = \frac{4.00 \times 10^4 \text{ kJ}}{20 \text{ min}} \left| \frac{1 \text{ min}}{60 \text{ s}} \right| \left| \frac{1 \text{ kW}}{1 \text{ kJ/s}} \right| = \underline{\underline{33.3 \text{ kW}}}$

b. Differential energy balance: $MC_v \frac{dT}{dt} = \dot{Q} \xrightarrow[\substack{M = 250 \text{ kg} \\ C_v = 4.00 \text{ kJ/kg}\cdot^\circ\text{C}}]{\substack{M = 250 \text{ kg} \\ C_v = 4.00 \text{ kJ/kg}\cdot^\circ\text{C}}} \frac{dT}{dt} = 0.001\dot{Q}(t)$
 $\underline{\underline{t = 0, T = 20^\circ\text{C}}}$

Integrate: $\int_{20^\circ\text{C}}^T dT = \int_0^t 0.001 \dot{Q} dT \Rightarrow T = 20^\circ\text{C} + \int_0^t \dot{Q} dt$

Evaluate the integral by Simpson's Rule (Appendix A.3)

$$\int_0^{600 \text{ s}} \dot{Q} dt = \frac{30}{3} [33 + 4(33 + 35 + 39 + 44 + 50 + 58 + 66 + 75 + 85 + 95) + 2(34 + 37 + 41 + 47 + 54 + 62 + 70 + 80 + 90) + 100] = 34830 \text{ kJ}$$

$$\Rightarrow T(600 \text{ s}) = 20^\circ\text{C} + (0.001^\circ\text{C/kJ})(34830 \text{ kJ}) = \underline{\underline{54.8^\circ\text{C}}}$$

c. Past 600 s, $\dot{Q} = 100 + \frac{10 \text{ kW}}{60 \text{ s}}(t - 600 \text{ s}) = t/6$

$$T = 20 + 0.001 \int_0^t \dot{Q} dt = 20 + 0.001 \left[\underbrace{\int_0^{600} \dot{Q} dt}_{34830} + \int_{600}^t \frac{t}{6} dt \right]$$

$$\Rightarrow T = 54.8 + \frac{0.001}{6} \left(\frac{t^2}{2} - \frac{600^2}{2} \right) \Rightarrow t(\text{s}) = \sqrt{12000(T - 54.8)}$$

$T = 85^\circ\text{C} \Rightarrow t = 850 \text{ s} = 14 \text{ min}, 10 \text{ s} \Rightarrow \underline{\underline{\text{explosion at } 10:14 + 10 \text{ s}}}$

$t = 0, V_0 = 400 \text{ L}$

KCl Balance:

$$\text{Accumulation} = \text{Input} - \text{Output} \Rightarrow \frac{dM_{\text{KCl}}}{dt} = \dot{m}_{i,\text{KCl}} - \dot{m}_{o,\text{KCl}} \Rightarrow \frac{d(CV)}{dt} = 1.00 \times 8.00 - 4.00C$$

$$\Rightarrow V \frac{dC}{dt} + C \frac{dV}{dt} = 8 - 4C \xrightarrow{dV/dt = 4} \frac{dC}{dt} = \frac{8 - 8C}{V}$$

$t = 0, C_0 = 0 \text{ g/L}$

- b.** (i) The plot of V vs. t begins at (t=0, V=400). The slope (=dV/dt) is 4 (a positive constant). V increases linearly with increasing t until V reaches 2000. Then the tank begins to overflow and V stays constant at 2000.

- (ii) The plot of C vs. t begins at (t=0, C=0). When t=0, the slope (=dC/dt) is (8-0)/400=0.02. As t increases, C increases and V increases (or stays constant) $\Rightarrow dC/dt = (8-8C)/V$ becomes less positive, approaches zero as $t \rightarrow \infty$. The curve is therefore concave down.

c. $\frac{dV}{dt} = 4 \Rightarrow \int_{400}^V dV = 4 \int_0^t dt \Rightarrow \underline{V = 400 + 4t}$

11.27 (cont'd)

When the tank overflows, $V = 400 + 4t = 2000 \Rightarrow t = 400$ s

11.28 (cont'd)

The plot of C_{S1} vs. t begins at $(t=0, C_{S1}=3)$. When $t=0$, the slope $(=dC_{S1}/dt)$ is $-0.08 \times 3 = -0.24$. As t increases, C_{S1} decreases $\Rightarrow dC_{S1}/dt = -0.08C_{S1}$ becomes less negative, approaches zero as $t \rightarrow \infty$. The curve is therefore concave up.

The plot of C_{S2} vs. t begins at $(t=0, C_{S2}=0)$. When $t=0$, the slope $(=dC_{S2}/dt)$ is $0.08(3-0) = 0.24$. As t increases, C_{S2} increases, C_{S1} decreases ($C_{S2} < C_{S1}$) $\Rightarrow dC_{S2}/dt = 0.08(C_{S1}-C_{S2})$ becomes less positive until dC_{S2}/dt changes to negative ($C_{S2} > C_{S1}$). Then C_{S2} decreases with increasing t as well as C_{S1} . Finally dC_{S2}/dt approaches zero as $t \rightarrow \infty$. Therefore, C_{S2} increases until it reaches a maximum value, then it decreases.

The plot of C_{S3} vs. t begins at $(t=0, C_{S3}=0)$. When $t=0$, the slope $(=dC_{S3}/dt)$ is $0.04(0-0) = 0$. As t increases, C_{S2} increases ($C_{S3} < C_{S2}$) $\Rightarrow dC_{S3}/dt = 0.04(C_{S2}-C_{S3})$ becomes positive $\Rightarrow C_{S3}$ increases with increasing t until dC_{S3}/dt changes to negative ($C_{S3} > C_{S1}$). Finally dC_{S3}/dt approaches zero as $t \rightarrow \infty$. Therefore, C_{S3} increases until it reaches a maximum value then it decreases.

c.

The plot of C_A vs. t begins at ($t=0, C_A=1$). When $t=0$, the slope ($=dC_A/dt$) is $-0.1 \times 1 = -0.1$. As t increases, C_A decreases $\Rightarrow dC_A/dt = -0.1C_A$ becomes less negative, approaches zero as $t \rightarrow \infty$. $C_A \rightarrow 0$ as $t \rightarrow \infty$. The curve is therefore concave up.

The plot of C_B vs. t begins at ($t=0, C_B=0$). When $t=0$, the slope ($=dC_B/dt$) is $0.2(1-0) = 0.2$. As t increases, C_B increases, C_A decreases ($C_B^2 < C_A$) $\Rightarrow dC_B/dt = 0.2(C_A - C_B^2)$ becomes less positive until dC_B/dt changes to negative ($C_B^2 > C_A$). Then C_B decreases with increasing t as well as C_A . Finally dC_B/dt approaches zero as $t \rightarrow \infty$. Therefore, C_B increases first until it reaches a maximum value, then it decreases. $C_B \rightarrow 0$ as $t \rightarrow \infty$.

The plot of C_C vs. t begins at ($t=0, C_C=0$). When $t=0$, the slope ($=dC_C/dt$) is $0.2(0) = 0$. As t increases, C_B increases $\Rightarrow dC_C/dt = 0.2C_B^2$ becomes positive also increases with increasing t $\Rightarrow C_C$ increases faster until C_B decreases with increasing t $\Rightarrow dC_C/dt = 0.2C_B^2$ becomes less positive, approaches zero as $t \rightarrow \infty$ so C_C increases more slowly. Finally $C_C \rightarrow 2$ as $t \rightarrow \infty$. The curve is therefore S-shaped.
